12

13 **Highlights:**

14 Framework developed to evaluate well-being impacts, applied to offshore wind industry

15 Links the five capital model, ecosystem services and well-being domains

16 Allows holistic evaluation of offshore wind industry impacts including sustainability

17 Acts a useful tool for organisation of evidence

18 Challenges remain, but framework transferrable to other industries and interventions

19

20 **Abstract**

21 Growing levels of energy consumption and concern over the environmental consequences
22 of energy production are leading to an increased investment in renewable energy
23 generation. Despite an important relationship between energy production, consumption
24 and well-being, little attempt has been made to provide a holistic assessment of how
25 renewable energy sectors can contribute to different aspects of human well-being. This
26 paper develops an impact evaluation framework that can be used to capture societal-level
27 impacts of change on primarily objective well-being and applies it to the case of the UK
28 offshore wind industry. As such, the framework goes beyond the traditional view of
29 economic, social and environmental impact assessment and evaluation capturing wider
30 aspects of societal costs and benefits as well as sustainable development. The framework
31 proves a useful tool for organising the available evidence and suggests a broadly positive
32 impact of the UK offshore wind industry. While further testing and refinement of the
33 framework is needed, it could be easily transferred for well-being assessment of other
34 industries and interventions.

35

36

37 **1. Introduction**

38 The consumption and generation of energy, in particular electricity, is closely related to
39 economic activity and other dimensions of human development (Ferguson et al., 2000;
40 Kaygusuz, 2007; OECD/IEA 2015). Energy supports jobs and productivity, but also
41 contributes to other human needs including food, shelter, health and education provision
42 (OECD/IEA, 2004). This impact on multiple dimensions of human life indicates another
43 important relationship: that between energy consumption and human well-being
44 (Pasternak, 2000; Castro-Sitiriche and Ndoye 2013).

45 Globally energy consumption is growing and with it are concerns over the environmental
46 consequences of energy production, especially its role in global climate change. Climate
47 change has been associated with a multitude of negative impacts on well-being (e.g. forced
48 relocations due to flooding; extreme weather disrupting road, rail and other services and
49 isolating communities; disruption to the production and supply of food impacting livelihoods
50 and food prices; Committee on Climate Change, 2011). To combat its effects, commitments
51 are being made to reduce greenhouse gas emissions and in some countries, to increase the
52 share of energy production from renewable sources. For example, the European Union's
53 Renewable Energy Directive (2009/28/EC) commits the EU to increasing the share of energy
54 consumption from renewable sources to 20% by 2020. Little has been done, however, to
55 provide a holistic assessment of how renewable energy sectors can contribute to different
56 aspects of human well-being.

57 Nationally recognised measures of well-being and societal progress have traditionally
58 focused on the economic measure of Gross Domestic Product (GDP) (La Placa and Knight,
59 2014). For example, energy industries in the UK contributed 3.3% of GDP in 2013, 28% of
60 which came from electricity including renewables (DECC, 2014a). GDP, however, is a
61 measure of production. It fails to capture the full cost of economic activity as social and
62 environmental costs are omitted (Stiglitz et al. 2009). An increase in GDP does not
63 compensate for a lack of satisfaction of basic needs, it neglects changes in income
64 distribution and ignores informal transactions that occur outside the market structure (van
65 den Bergh, 2009). Consequently it is a poor measure of social welfare.

66 How to accurately measure well-being remains under dispute. Well-being is a complex,
67 multi-dimensional concept for which no unified definition has been agreed (Dodge et al.,
68 2012; La Placa et al., 2013). It is assumed to be comprised of both objective and subjective
69 domains distinguishing between material living conditions and quality of life (OECD, 2011a).
70 Nevertheless, many governments, international and supranational bodies are now
71 committed to measuring well-being more broadly (e.g. OCED, 2011a; Commission of the
72 European Communities, 2009).

73 This paper develops an impact evaluation framework that can be used to capture societal-
74 level impacts of change on primarily objective well-being. The framework emerged from a
75 project undertaken for The Crown Estate (Hattam et al., 2015a), on which this paper builds

76 by extending discussion of the theoretical concepts, merits and limitations of the approach.
77 The framework links well-being domains with the five capitals model (Forum for the Future,
78 1990), which describes the assets from which the goods and services required to sustain
79 well-being are derived. The framework also incorporates the concept of ecosystem services,
80 to support understanding of the social and economic consequences of changes in natural
81 resource provision. By combining these three elements, the impacts of interventions can be
82 holistically assessed for the first time in terms of well-being.

83 The framework is applied to the case of the UK offshore wind industry, as an example of
84 how it could be applied to any policy intervention or investment. The paper is structured as
85 follows: section 2 introduces the well-being impacts framework; section 3 describes the
86 offshore wind industry in the UK and the application of the framework to it; section 4
87 presents the results; section 5 discusses the merits and limitations of the approach and
88 section 6 provides final concluding remarks.

89

90 **2. Evaluating well-being impacts: a framework**

91 The focus on well-being, as opposed to economic, social and environmental impacts,
92 emphasises a holistic approach to impact evaluation. Sectoral divisions are rejected and the
93 multiplicity of factors impacting upon the individual and society, and how they are
94 interconnected, is recognised (White, 2010). The framework developed (Figure 1) uses a
95 capital-based approach to understanding well-being and how it is changing. It builds on the
96 framework developed by the OECD for its biannual study of “How’s life? Measuring Well-
97 Being” (OECD, 2011b; 2013; 2015) in which well-being is assessed across OECD member
98 states. The “How’s life?” framework arose from the recommendations of the Commission
99 on the Measurement of Economic Performance and Social Progress (Stiglitz et al., 2009) and
100 the Conference of European Statisticians on measuring sustainable development (UNECE,
101 2014). Well-being is not viewed as a fixed destination or outcome, but as a process, with
102 conceptions of well-being changing over time (White, 2010).

103

104 **Figure 1 here**

105

106 **2.1. Five capitals**

107 The capital approach to well-being is based on the premise that well-being is generated
108 from stocks of capital (or assets) and the ability of individuals and society to use these
109 capitals (OECD, 2011a). This model emerged from debates on the steady-state economy and
110 sustainable development during the latter part of the twentieth century, which focused on
111 the maintenance of stocks of capitals, rather than the flows of goods and services (e.g. GDP)
112 from them (e.g. Boulding, 1966; Schumacher, 1972; Ekins, 1992). It is assumed that capitals
113 can be stored, transformed, exchanged or used to create a flow of goods and services that
114 in turn lead to a change in well-being (Rakodi, 1999). The OECD (2011a) framework focuses

115 on four types of capital: natural, economic, human and social capital. It recognises that the
116 sustainability of well-being is dependent upon the preservation of these four capitals. These
117 four capitals influence a broad range of well-being domains, persist to varying degrees over
118 time and require investment and management if they are to be maintained (OECD, 2015).
119 The four capitals model has a long history in the debate over sustainable development

120 To explore the well-being impacts of the offshore wind industry, a modified version of the
121 OECD framework is applied. Five forms of capital are distinguished, with economic capital
122 disaggregated into financial and manufactured capital, following Porritt (2007). This
123 disaggregation allows a distinction to be made between the objects that humans create and
124 that can themselves generate well-being (manufactured capital), and the representation of
125 the value and productive power of the other forms of capital (i.e. financial capital). The five
126 capitals are defined as:

- 127 • **Financial capital:** derived from revenues generated through sales and determined by
128 production rates, market prices and costs of production (Moran et al., 2013).
- 129 • **Manufactured capital:** comprising goods or assets that contribute to the production
130 process or the provision of services, rather than being part of the output itself. It
131 includes for example tools, machinery, buildings and infrastructure (Moran et al., 2013).
- 132 • **Human capital:** constitutes health, knowledge, skills and capabilities of individuals, the
133 workforce and related communities (Schultz, 1961).
- 134 • **Social capital:** refers to networks together with shared norms, values and
135 understandings that facilitate cooperation within or among groups (Cote and Healy,
136 2001).
- 137 • **Natural capital:** encompasses natural resources as well as the processes needed to
138 sustain life and produce goods and services (Forum for the Future, 1990).

139

140 **2.2. Assessing natural capital through ecosystem services**

141 Considerable effort has been given to understanding the links between natural capital and
142 human well-being through ecosystem services (e.g. via the Millennium Ecosystem
143 Assessment (2003), The Economics of Ecosystems and Biodiversity initiative (2010) and
144 many national ecosystem service assessments such as the UK National Ecosystem
145 Assessment (2011) and the 2014 UK National Ecosystem Assessment – Follow On).
146 Ecosystem services are considered to be “the direct and indirect contributions of
147 ecosystems to human well-being” (TEEB, 2010). By assessing changes in ecosystem services
148 the links between environmental change and human well-being are made more explicit
149 (Millennium Ecosystem Assessment, 2003). The exact form of the relationship between
150 ecosystem services and human well-being is unknown, but a loss of ecosystem services is
151 assumed to have a negative impact on human well-being through a loss of the benefits that
152 these services generate (Butler and Oluoch-Kosura, 2006). The natural capital component in

153 the framework has therefore been augmented to include the four functional groups of
154 ecosystem services defined by the Millennium Ecosystem Assessment (2003):

- 155 • **Provisioning services:** the products obtained from ecosystems, including food, fibre,
156 fuel, genetic resources, medicines and pharmaceuticals, ornamental resources, and
157 freshwater.
- 158 • **Regulating services:** the benefits obtained from the regulation of ecosystem processes
159 including air quality, climate regulation, water regulation, erosion control, water
160 purification and waste treatment, regulation of human diseases, biological control,
161 pollination, and storm protection.
- 162 • **Cultural services:** the nonmaterial benefits people obtain from ecosystems including
163 cultural diversity, spiritual and religious values, knowledge systems, education values,
164 inspiration, aesthetic values, social relations, sense of place, cultural heritage values, and
165 recreation and ecotourism
- 166 • **Supporting services:** the services that are necessary for the production of all other
167 ecosystem services, including primary production, production of atmospheric oxygen,
168 soil formation and retention, nutrient cycling, water cycling, and the provision of habitat.

169

170 **2.3. Inclusion of governance**

171 In a further modification of the OECD framework, the governance context is explicitly
172 incorporated. The term governance is used in many ways, but broadly speaking refers to the
173 process of governing, as undertaken by a variety of social actors including governments,
174 private companies, non-governmental organisations and service providers (Bevir, 2012).
175 There is an argument that governance can be conceived of as a form of social capital (e.g.
176 World Bank, 1997), but here it is considered as a distinct entity. The governance structure,
177 or enabling environment, in which these capitals are located plays a role in well-being,
178 determining how capital can be used (Kula et al., 2008). It influences the access of
179 individuals and society to the different capitals, how they are exchanged and the level of
180 return on investments made into each of these capitals. Governance also defines the roles,
181 responsibilities, rights and relationships of the different organisation and institutions that
182 affect the use of capitals (Kooiman, 2003).

183 Governance can play a key role in creating or reducing uncertainty. In the existing neo-
184 liberal economic climate, the role of governance is to support the market in facilitating
185 growth in sectors of interest (Porrit, 2007). The degree of support offered may influence the
186 level of investment in an industry, thereby determining its growth. An increase or decrease
187 in investment will change the extent to which an industry impacts on well-being via its
188 effects on the five capital stocks.

189

190 **2.4. Linking the five capitals to well-being**

191 Following the OECD framework, stocks of capital are assumed to sustain various dimensions
192 of well-being. Understanding how well-being changes requires an understanding of how the
193 different capitals, which make up the systems in which individuals and households are a
194 part, also change (Stiglitz et al., 2009; OECD, 2011). Changes in well-being are therefore
195 closely linked to the sustainable use of the five capitals.

196 It is often unclear how capital stocks actually impact well-being and whether positive
197 changes in the five capitals result in positive impacts on well-being (Costanza et al., 2008;
198 Stiglitz et al., 2009). The interlinkages are complex and more than one capital can affect the
199 same well-being domains. It is often assumed that there is a positive relationship between
200 changes in capital stocks and well-being, and that increases (decreases) in capital stocks will
201 increase (decrease) well-being. In the context of offshore wind farms in Germany, Busch et
202 al. (2011) make this positive relationship assumption noting that offshore wind-farms (use
203 of natural capital) could lead to increases in employment (human capital), which could in
204 turn improve economic well-being.

205 The OECD framework incorporates well-being indicators that focus on individual and
206 household well-being, rather than aggregate conditions, recognising that the economy-wide
207 situation may be a poor reflection of household or individual well-being. It also concentrates
208 on well-being outcomes, rather than inputs, as there is an imperfect relationship between
209 the two (e.g. health expenditure may be a poor predictor of individual health status; OECD,
210 2011). The indicators used comprise a mixture of objective and subjective aspects of well-
211 being, reflecting individual capabilities as well as material outcomes.

212 Building on the OECD framework, many individual countries have also begun to develop
213 their own well-being indicators. The UK's Office for National Statistics (ONS), through the
214 Measuring National Well-being Programme (Randall et al., 2014), considers ten different
215 well-being domains (the economy, what we do, where we live, personal well-being,
216 education and skills, personal finance, health, our relationships, the natural environment,
217 governance). For each of the domains, a series of individual or household level indicators
218 have been developed (e.g. the health domain includes life expectancy, long term illness and
219 satisfaction with personal health). To ensure a good fit to a UK case study, the OECD
220 indicators are replaced by the ONS well-being domains.

221 Many of these well-being domains are closely linked, and change in one may feedback to
222 another. For example, employment, education and economic status are known to have a
223 relationship with health (Bartley, 1994; Ross and Wu, 1995; Smith, 1999) and there is a
224 consistently strong relationship between health (both physical and psychological) and
225 subjective well-being (Dolan et al., 2008). The direction of causation and why the
226 relationships occur are hotly debated (Smith, 1999; Dolan et al., 2008). The relative
227 importance of the different domains to well-being may also change over time (Costanza et
228 al., 2008).

229

230 **3. Offshore wind case study**

231 The adoption of the EU Renewable Energy Directive (2009/28/EC) commits the UK to a
232 target of 15% of electricity consumption from renewable sources by 2020. Offshore wind
233 energy is considered the main resource for the UK to meet this targets (DECC, 2013). By the
234 end of 2015, the UK had 28 offshore wind farms projects containing 1,465 turbines with an
235 installed capacity of 5.1 GW (RenewableUK, 2016a). It is expected to achieve over 10 GW by
236 2020 (UKTI 2014). In 2015, offshore wind farms provided 5.2 per cent of the UKs energy
237 demand (RenewableUK, 2016b).

238 Application of the framework was undertaken using a two stage process. Stage one involved
239 searching both peer reviewed and grey literature for available evidence on the actual
240 impacts of the offshore wind industry on the five capitals. Anticipated future impacts were
241 only noted where relevant. While the benefits arising from the use of renewable energy to
242 future climate change are recognised, assessment of these impacts is beyond the scope of
243 this review.

244 Stage two focused on assessing the evidence gathered in terms of well-being impacts and
245 associating the evidence collected for each capital with the ONS well-being domains. No
246 attempt was made to link changes in capitals to the specific well-being indicators defined by
247 the ONS for each domain. The evidence available in the literature was considered
248 insufficient to assess changes at this fine grained individual/household level. Identifying
249 these linkages is challenging because well-being domains do not exist independent of each
250 other. Furthermore, given the evidence available, unidirectional relationships between the
251 offshore wind industry, capitals and well-being are difficult to describe. Also, the indicators
252 provided by the ONS are not exhaustive. This association between the evidence, capitals
253 and well-being domains was therefore based on expert judgment.

254 To avoid repetition, capitals were linked to the well-being domain(s) for which a change in
255 the capital was expected to have the greatest impact or for which some evidence existed.
256 For example, impacts on financial capital were only linked to the well-being domain of
257 economy. While it is recognised that financial capital change is likely to impact upon other
258 well-being domains, evidence for this was unavailable. The process of linking capitals to
259 well-being domains was iterative with new links recognised as the literature review
260 progressed.

261

262 **4. Results**

263 Table 1 presents the links identified between the five capitals, the ONS well-being domains
264 and the evidence available for the offshore wind industry. Despite the recognition that well-
265 being indicators need to focus on the individual or household level (OECD, 2011), limitations
266 in the data available meant that the evidence identified focused more broadly on societal or
267 community level effects. The review therefore evaluates UK-wide and regional effects,

268 examining the meaning of this for individual and household well-being only where evidence
269 permits.

270 Where possible, the impacts evaluated were linked to outcomes (i.e. the result of a capital
271 change) as opposed to inputs (i.e. the cause of the capital change). Data limitations,
272 however, meant that some inputs (e.g. investments in financial capital) have also been
273 captured and well-being impacts assumed as a result. Data limitations and an absence of a
274 baseline for both the capitals and well-being domains have meant that only qualitative
275 assessments of change were made, identifying whether well-being changes could be
276 considered positive or negative; where possible, quantitative accounts are given.

277

278 **Table 1 here**

279

280 **4.1. Financial capital**

281 Changes in financial capital were primarily linked to the well-being domain of the economy.
282 Operating offshore wind farms were estimated to contribute approximately £1 billion to the
283 UK economy in 2013, representing 0.2% of GDP (ORE Catapult, 2014). This is the result of
284 both private and public investment. Between 2010 and 2013 an estimated £6.9 billion was
285 invested in the offshore wind industry (REA, 2014). This is compared to an estimated £7.6
286 billion in onshore wind, £6.4 billion in solar, £6.3 billion in biomass and bioenergy, £0.2
287 billion in hydro, £0.1 billion in tidal and wave and £1.4 billion in other renewables for the
288 same period (REA, 2014).

289 There is considerable support for the offshore wind industry, which in turn is generating
290 economic activity, although the well-being impact of which cannot be assessed given
291 available evidence. For example, supply chain programmes have been developed in attempt
292 to capture the maximum gains for the UK economy. In 2013, only 43% of lifetime costs
293 associated with UK offshore wind farms was maintained domestically (ORE Catapult, 2014),
294 compared to 70% for North Sea oil and gas (HM Government, 2013). There are now a
295 number of initiatives, organisations and advice networks that aim to grow the UK supply
296 chain. These include the Advanced Manufacturing Supply Chain Initiative, GROW: Offshore
297 Wind Fund and the Offshore Wind Investment Organisation, on top of substantial private
298 investment (£300 million between 2012 and 2014; HM Government, 2014). In England, six
299 Centres for Offshore Renewable Engineering (CORES) have also been strategically
300 established (UKTI, 2014).

301 Technological innovation has received support on a UK-wide scale and with a regional focus.
302 For example, the UK's Department of Energy and Climate Change (DECC) allocated
303 £30million for technological innovation and The Green Investment Bank has invested £1bn
304 in offshore wind during construction and operation phases. Public-private partnerships have
305 been set up to accelerate knowledge building. Two UK government departments (DECC and
306 Business, Industry and Skills), together with the UK research councils and organisations such

307 as the Energy Technology Institute, the Technology Strategy Board and the Carbon Trust
308 have spent in excess of £100 million (2011-2015) to support offshore wind through the Low
309 Carbon Innovation Coordination Group (LCICG, 2012).

310 Financial support also takes the form of subsidies, which have been used to create certainty
311 and incentivise investment in the offshore wind industry. In 2013, total UK energy subsidies
312 were £3.6 billion for gas, £2.3 billion for nuclear and £3.1 billion for renewables
313 (Environmental Audit Committee, 2014). There is currently uncertainty over the future of
314 subsidies for the industry, with the October 2015 round of Contracts for Difference (a
315 subsidy scheme which pays the renewable energy supplier the difference between the long-
316 term strike price for electricity and the market price) being postponed (Nicholls, 2015).

317

318 **4.2. Manufactured capital**

319 Evidence from the literature indicates that changes in manufactured capital as a result of
320 the offshore wind industry can be linked primarily to the well-being domains of economy
321 (via manufacturing capacity), where we live (via infrastructure) and what we do (via jobs).
322 Manufacturing related to the offshore wind industry, however, is limited within the UK,
323 although investment in the region of £110 billion is expected by 2020 (HM Government,
324 2014). Impacts on well-being may therefore be relatively small via manufactured capital and
325 can only be assumed to result from the inputs described below.

326 Within the UK, only Siemens is currently producing and assembling turbine components,
327 although turbines of up to 2MW have been assembled in the UK in the past (BVG, 2014).
328 There is only one tower production facility in the UK (Wind Towers Scotland) at
329 Campeltown, Argyll; the majority of towers are imported primarily from Europe. This may
330 change in the near future, for example an overseas subsidiary of South Korean CS Wind
331 Corporation is being supported to build an offshore wind turbine tower manufacturing
332 facility on Humberside. It is anticipated that this facility will create up to 200 direct jobs with
333 others in the supply chain (HM Government/British Embassy Seoul, 2015). Other companies
334 are also investing along the Humber. The Association of British Ports (ABP) is investing £310
335 million in dockside regeneration, which is hoped to create 100 jobs with more in the supply
336 chain, and Siemens has committed to a new manufacturing facility on the Humber,
337 producing blades and nacelles (UKTI, 2014).

338 It is not only investment in manufacturing facilities that is generating employment and
339 income. There has also been investment in ports in support of the construction, operation
340 and maintenance of OWFs (HM Government, 2012). For example, Barrow, Grimsby,
341 Lowestoft, Mostyn, Ramsgate, Workington and Belfast have all attracted investments from
342 the offshore wind industry. This investment, however, is in line with investments made by
343 other industries such as the automotive, biomass, container transport industries.

344 An additional benefit arising from the offshore wind industry is the extension of the
345 electricity transmission network through the installation of cables, seabed substations and

346 upgrades to the grid to accept the variable input of electricity generated from wind
347 turbines. Further investments, such as offshore grids, reinforcement of the power
348 transmission capacity between Scotland and England (O’Keeffe and Haggett, 2012), and
349 additional connections with other countries (see for example, SKM, 2010) are also
350 underway. This grid modernisation is considered critical for maintaining energy security and
351 ensuring the country meets its wider energy objectives (DECC, 2014b).

352

353 **4.3. Human capital**

354 Human capital draws on the ability of people to develop intellectually and work in
355 environments which support individual wealth creation (Forum of the Future, 1990). It is
356 expected that improvement in human capital will contribute directly to well-being through
357 the domains of what we do (through employment), education and skills, personal finance
358 and health.

359 Generic apprenticeships, bespoke training courses and research at centres of excellence
360 support skills development in the offshore wind industry. The offshore wind industry has
361 made substantial investment into training, research and development. There are a number
362 of industry-university partnerships (e.g. the £12.5 million Gamesa Offshore Wind
363 Technology Centre in Glasgow), university centres (e.g. the Offshore Renewables Institute
364 formed by the Universities of Dundee, Aberdeen and Robert Gordon University), bespoke
365 centres of excellence (e.g. the Offshore Renewable Energy Catapult) and other public-
366 private partnerships (e.g. the Energy Technologies Institute and the Carbon Trust’s Offshore
367 Wind Accelerator). These, together with experiences from OWF development, are leading to
368 an accumulation of skills in the UK in the planning, construction, operation and maintenance
369 of offshore wind farms. Many countries (e.g. the US, Canada, South Korea, Japan, India,
370 China and Taiwan) are now seeking to learn from the experiences in the UK (UKTI, 2014).

371 In 2013, 6,830 people were directly employed by the offshore wind industry up from 3,151
372 in 2010 (RenewableUK, 2013). This compares to 5,005 in the UK coal industry in 2013
373 (Pettinger, 2012). Approximately 30% of jobs are in construction and installation, 25% in
374 planning and development, 18% in support services, 16% in operations and maintenance
375 and 10% in manufacturing. Estimates suggest that a further 7,000 people are employed
376 indirectly along the offshore wind supply-chain (UKTI, 2014).

377 Jobs in the offshore wind industry are considered to be high skilled (Cambridge
378 Econometrics, 2012). Wages reflect this, ranging from £19,706 for skilled production
379 operatives to £102,837 for heads of manufacturing (HM Government, 2012). Unfortunately
380 median gross annual wages for the offshore wind industry are unavailable making
381 comparisons to other sectors difficult.

382 It is not clear whether the development of offshore wind is leading to lost or displaced jobs
383 in other sectors such as fisheries and tourism. Little work has explored the effects of OWF
384 on tourism. Anecdotal evidence indicates the continued existence of a tourism industry

385 close to an OWF site (Keuhn, 2005). Impacts on fisheries also appear limited, with some
386 displacement occurring because of concerns over gear entanglement (Gray et al., 2016).
387 Detailed assessment of changes in overall effort and landings, or wider implications for
388 fisheries (such as the effect of any increased fuel expenditure on profitability) is currently
389 lacking.

390 Health is the final component of human capital considered. Evidence of health impacts is
391 scant, but benefits may accrue in terms of air quality improvements and mitigation of the
392 negative effects of climate change (Ison and Pearce-Smith, 2009). There are occupational
393 health hazards but it is not possible to attribute these to the offshore wind industry
394 specifically. For example, in 2005 there was a total of 6 accidental and 13 occupational
395 deaths over all electricity generating technologies (Markandya and Wilkinson, 2007).
396 Impacts on the seascape may also contribute to health impacts. Attractive landscapes have
397 been shown to provide health and well-being (Abraham et al., 2010), but the primary
398 negative effect of OWFs is considered to be the impact on the seascape (Devine-Wright and
399 Howes, 2010; Gee and Burkhard, 2010; Waldo, 2012). This suggests that OWFs may cause a
400 loss of human capital to some.

401

402 **4.4. Social capital**

403 The concept of social capital affects our relationships and encompasses notions of
404 community spirit, networks, and social resources (i.e. it is an attribute of communities as
405 opposed to individuals). Evidence available suggests that changes to social capital arising
406 from the offshore wind industry can be linked to personal well-being, where we live and our
407 relationships.

408 Generally there is strong support for OWFs (Ladenburg, 2008, 2010; Karlstrøm and Ryghaug,
409 2014; Hattam et al., 2015b). This is motivated by beliefs that may contribute to social capital
410 including that the offshore wind industry creates jobs and leads to local economic growth
411 (Gee and Burkhard, 2010; Vanhulle et al., 2010; Waldo, 2012). While negative opinions are
412 also documented, they are not typically related to issues of social capital (Busch et al., 2011;
413 Waldo, 2012; Teisl, 2015).

414 Perceptions of personal and community impacts and benefits are important for explaining
415 public support for renewables projects. Offers of support from developers, commonly
416 relating to community projects, are not always met with enthusiasm, however. Support in
417 terms of local jobs and contracting is generally unproblematic and uncontroversial, but the
418 provision of direct financial contributions to communities may be perceived as bribery.
419 Nevertheless, experience of positive community benefits has been shown to increase the
420 level of support expressed for a proposed OWF development (Cass et al., 2010).

421 Direct investments into communities from offshore wind activities are substantial. For
422 example, the offshore wind industry, via The Crown Estate and HM Treasury, feeds into the
423 Coastal Communities Fund, which has committed £45 million to 63 seaside towns in England

424 and Scotland (RenewableUK, 2015). The CORES have also raised between £5.7 million and
425 £33 million for investment in projects, such as transport and housing, within their localities
426 (HM Government, 2011; DCLG, 2014). In addition, individual developers have provided
427 financial support to communities local to specific OWFs. These include the £19 million fund
428 established by RWE to support Northern Welsh communities (RWE, 2014) and the £235,000
429 per annum pledged for communities within Liverpool Bay by Dong Energy (Grantscape,
430 2015). It has not been possible to identify the well-being outcomes arising from these
431 investments, but community level changes are likely to impact on social capital.

432 The OWF industry is also developing social capital through the establishment of groups and
433 networks. Examples include the Offshore Wind Energy Council, a forum for representatives
434 from industry and Government, and RenewableUK, the renewable industry's umbrella body.
435 Regional groups, such as Energi Coast in the North East of England, also exist, supporting
436 regional renewables supply chains. Social capital is also built through the formation of
437 groups that oppose, or support, the developments. The Atlantic Array, proposed for the
438 Bristol Channel for example, led to the formation of several active opposition groups.
439 Elsewhere (e.g. for the Navitus Bay OWF in Dorset, which did not gain consent), there is also
440 anecdotal evidence of co-ordinated support (e.g. through campaign groups such as
441 38degrees) and of the 400 people who gathered to protest in Swanage in January 2013, 100
442 were in favour of the wind farm (The Guardian, 2013).

443

444 **4.5. Natural capital**

445 Natural capital links to the domain of the natural environment, and contributes to human
446 well-being through, for example, the availability of food and raw materials (provisioning
447 services), protection from hazards such as flooding, erosion and pollution (regulating
448 services) and recreational opportunities (cultural services). All of these are underpinned by
449 complex webs of species and habitat interactions (supporting services). While evidence
450 exists on the localised impacts of OWF on components of natural capital, there are still gaps
451 in the empirical evidence. It may not always be possible to attribute change in natural
452 capital to the impacts of OWF and impacts are often species or location specific.
453 Furthermore, the existing evidence is not sufficient to infer potential impacts on well-being,
454 beyond the recognition that changes to ecosystem services can be assumed to result in
455 changes in human well-being.

456 There is no unequivocal evidence that OWFs affect provisioning services through noise or
457 electromagnetic field effects harming edible species. There is, however, a growing literature
458 that suggests OWFs may have other effects, both positive and negative on the fisheries
459 ecology of commercial species, although these are often mixed or uncertain (Bergström et
460 al., 2013; Reubens et al., 2013; Vandendriessche et al., 2014; Ashley et al., 2014).

461 The widely-reported colonisation of turbine foundations by mussels (e.g. Wilhelmsson and
462 Malm, 2008) has the potential to influence regulating services. Mussels have an increased

463 capacity to sequester carbon (at least in the short-term) and to remediate waste and toxins
464 in the water column compared to the sediments surrounding OWFs. A further positive effect
465 is the provision of nursery habitat (Leonhard and Pedersen, 2006; Reubens et al. 2013).
466 Conversely, concern has been raised about OWFs acting as stepping stones and facilitating
467 the spread of non-native species (Degraer and Brabant, 2009; de Mesel et al., 2015), an
468 issue that has a demonstrable negative effect on wellbeing (Börger et al., 2014).

469 Charismatic species such as marine mammals and seabirds are highly valued by society
470 (Richardson and Loomis, 2000), and are associated with the less tangible cultural services
471 (such as spiritual wellbeing and inspiration). There is a relatively large volume of research on
472 the effects of OWFs on marine mammals and seabirds, which shows short-term
473 displacement of marine mammals during pile driving (e.g. Brandt et al., 2011; Brasseur et
474 al., 2012; Dähne et al., 2013), although this may reflect the use of mandatory measures
475 designed to discourage mammals from entering the construction zone. No evidence of harm
476 to individual animals or of long-term or population level effects was found.

477 The interaction of OWFs and seabirds varies between species and between OWFs and so
478 cannot be effectively generalised. Some modifications in seabird behaviour have been
479 observed, particularly avoidance of turbines (e.g. Krijgsveld et al., 2011; Plonczkier and
480 Simms, 2012), as have changes in abundance, with evidence of both increasing (Vanermen
481 et al., 2013; Walls et al., 2013) and decreasing (Petersen et al., 2006; Degraer and Brabant,
482 2009) populations. Seabird strikes and mortality have also been reported, but at very low
483 levels (Newton and Little, 2009).

484 Wider changes to species abundance, diversity and community composition have also been
485 reported from OWF studies (e.g. Birklund, 2005; Wilhelmsson and Malm, 2008). These may
486 alter the provision of supporting services, but the potential effect of any such changes on
487 well-being is unknown.

488

489 **4.6. Governance**

490 Governance is explored here in the context of decision-making for OWF development and
491 the role that the state and other influential actors have taken in this process. Having trust in
492 this process and how this process affects our relationships are important contributors to
493 well-being. Prior to 2007, the UK Government offered little support to the offshore wind
494 industry. A complex planning and consenting process led to slow development (Markard
495 and Petersen, 2009; Gibson and Howsam, 2010), making the industry economically
496 unattractive (Ochieng et al., 2014). Following the UK Climate Change Act 2008 and the
497 introduction of renewable energy targets via the Renewable Energy Directive (2009/28/EC)
498 there has been rapid deployment and changes to the licensing and consenting processes
499 (Kern et al., 2014). Planning has now been streamlined and, for applications for OWFs with
500 capacity over 100MW, the decision to award a development consent order is taken by the

501 relevant Minister (e.g. Secretary of State for Energy and Climate Change or Secretary of
502 State for transport in the case of port development).

503 Planning inquiries for OWFs cannot be called for by local authorities as OWFs are not within
504 local authority boundaries (Toke, 2011). While consultations are undertaken with local
505 communities, Haggett (2008) found that many considered these to be cosmetic and to be
506 more about information distribution than dialogue. This has led to distrust in government
507 and local authorities arising from a sense that the Government is supporting wind energy
508 developments through subsidies, or is being forced to support wind energy as a result of EU
509 policy. Big business is seen to be favoured over the wishes of local communities and the
510 environment. Barry et al. (2008) show how opposition groups often position themselves not
511 as fighting against wind farms *per se*, but as fighting on the side of the democratic process.

512 To overcome this distrust it has often been assumed that providing the public with more
513 information is the solution (e.g. Ellis et al., 2007; Aitken, 2010). There is no clear
514 relationship, however, between knowledge and acceptance of wind farms and some
515 consider the consultation process is ineffectual (Kerr et al., 2014). There is a perception
516 within communities that developers only engage with them as an attempt to manage or
517 overcome opposition (Aitken, 2010).

518 Although evidence indicates that offshore wind farms have limited impacts on the fishing
519 industry, fishermen are often reported to distrust both developers and regulators. This
520 largely arises from previous experiences with the planning process that have resulted in
521 activity restrictions (Mackinson et al., 2006). Like local communities, fishermen often view
522 consultation as tokenism on the part of the developer (Gray et al. 2005; de Groot et al.
523 2014). Nevertheless, the shape of the relationship between developers and the fishing
524 industry varies with OWF and developer.

525

526 **5. Discussion**

527 The application of the framework developed for this review enables a holistic evaluation of
528 the impacts of the offshore wind industry on human well-being in the UK. *Ex post* evaluation
529 of the impacts resulting from investments, such as those made by the offshore wind
530 industry, is essential for effective decision-making. Evaluations can assess how effective an
531 investment is, not only in terms of achieving its desired outcomes, but also with respect to
532 identifying wider and unintended outcomes (HM Treasury, 2011).

533 In contrast to *ex ante* impact assessments, which are enshrined in legislation (e.g. the
534 European Union's Environmental Impact Assessment Directive 2011/92/EU) and are
535 undertaken before a decision, investment or policy has been made, there is limited legal
536 requirement for *ex post* impact evaluations. Often only post-construction environmental
537 monitoring is required to validate assertions made in environmental statements, given the
538 lack of peer-reviewed evidence on the impacts of offshore energy devices (Walker and Judd,
539 2010). There is no obligation, however, to monitor and evaluate the post construction social

540 and economic impacts of offshore wind farm developments. This is despite the social and
541 economics promises OWF developers make in their planning applications. The small number
542 of economic evaluations that have been undertaken have been driven by industry and
543 environmental NGOs (e.g. Cambridge Econometrics, 2012; ORE Catapult, 2014). The
544 absence of wider evaluations is a missed opportunity for planners to understand the full
545 extent of the impacts of their decisions (both positive and negative), as well as for
546 developers to indicate the impacts of their industry beyond the delivery of renewable
547 energy.

548

549 **5.1. Merits of the framework**

550 There is growing interest worldwide in the assessment of well-being change at the individual
551 and societal level (e.g. the Bhutanese Gross National Happiness Index, the Canadian Index of
552 Wellbeing). These evaluations are rarely undertaken for the impact of policies and other
553 interventions, such as investments. This may in part be due to the difficulties in linking
554 policies and interventions to well-being outcomes, but the framework presented here
555 indicates how well-being evaluations could be made.

556 While this framework is only a first step towards evaluating well-being impacts, it goes
557 beyond the traditional view of economic, social and environmental impact assessment and
558 evaluation. These impacts are often evaluated independently, failing to capture the
559 interlinkages between them or their links to capital assets and human well-being. For
560 example, the Environmental Impact Assessment process is a crucial component of planning,
561 but has been criticised for its emphasis on local, and predominantly negative, impacts
562 (Smart et al., 2014). A framework that allows for a more holistic assessment of wider
563 societal costs and benefits therefore represents an important step forward. While it has
564 been used to evaluate impacts in this study after investment, it has potential for use prior to
565 developments taking place. The importance of the framework is in highlighting the interplay
566 between different types of capital and how the favouring of one capital may be at the
567 expense of others. It may be particularly useful in situations where more common methods
568 of evaluation (e.g. Cost Benefit Analysis or Multi-Criteria Analysis) are not applicable as
569 impacts are not quantifiable and/or are incommensurate (Ekins et al., 2008).

570 Such a framework is also more aligned with changing approaches to management that
571 reflect the two-way interaction between people and the environment, and seek to assess
572 the trade-offs necessary to achieve societal goals (Loomis and Paterson, 2014). While it has
573 not been possible in this study to identify and assess all well-being impacts, the framework
574 does encourage the evaluation of impacts on multiple dimensions of well-being and
575 provides a structure for this evaluation.

576 The emphasis on capitals also links to the concept of sustainable development (Stiglitz et al.,
577 2009). Sustainable development necessitates the maintenance or improvement of the five
578 capitals, upon which future well-being is dependent. Policies, programmes and investments

579 that can demonstrate a positive impact on the five capitals will therefore likely benefit
580 future well-being and intergenerational equity as well. There are numerous examples of the
581 evaluation of sustainability of development using a capitals framework, for example,
582 assessing urban sprawl in Prague (Balžek et al., 2008), regional development in Poland
583 (Gorzalek et al., 2008), for mining and pastoralism in Australia (Moran et al., 2013) and rural
584 livelihoods in developing countries (e.g. Bebbington, 1999). The framework's applicability at
585 multiple scales is therefore possible, although the data needs at different scales will be
586 distinct.

587

588 **5.2. Limitations**

589 The framework and its application to the offshore wind case study are not without their
590 limitations. The framework itself is challenged by the underlying assumption that an
591 increase (decrease) in a capital stock may lead to a corresponding increase (decrease) in
592 well-being. The shape of the relationship (or more likely relationships) between capital
593 assets and well-being is still to be determined. Despite the vast body of literature examining
594 and documenting the determinants of well-being (see e.g. Cote and Healy, 2001; Dolan et
595 al., 2008; Stiglitz et al., 2009), identifying the reasons behind changes in well-being
596 indicators remains challenging.

597 Associated with this is a lack of understanding about how the different capitals can be
598 traded-off against each other and what the implications of these trade-offs have for well-
599 being. The extent to which gains in one capital can compensate for losses in another are
600 unknown and has been subject to considerable debate (see e.g. Dobson, 1996). There has
601 been a long history of assuming that manufactured capital can compensate for other
602 capitals, at the expense, particularly, of natural and social capital, the consequences of
603 which are now becoming apparent. In addition, the degree to which such trade-offs may be
604 individual specific and temporally and spatially limited requires further investigation. The
605 impacts of capital change on well-being may differ by person. For example, improvements in
606 infrastructure and employment resulting from the construction of an OWF may benefit the
607 well-being of some (e.g. those with engineering backgrounds), but result in well-being losses
608 for others (e.g. individuals who consider their view has been spoilt). This raises equity
609 questions over whose well-being should be measured and whether assessment should be
610 undertaken at the individual or collective level.

611 An additional challenge for assessing well-being change is the lack of data on the outcomes
612 of investments. Considerable investment by the offshore wind industry and the UK
613 Government has been made in financial, manufactured and human capital. This is assumed
614 to be linked to a well-being gain, but the outcomes of these investments remain to be seen.
615 This is partly as a consequence of the recentness of the investments but also because of a
616 lack of access to the appropriate data by this study. Improving upon this assessment would
617 require additional data (primary and secondary) collection, potentially focused on specific
618 case study locations.

619 The absence of a well-being baseline or capital accounts against which to measure change is
620 also problematic. While the review has been able to show a general direction of change
621 resulting from the development of the offshore wind industry, it has not been possible to
622 quantify the magnitude of this change. In the absence of a counterfactual, it is also
623 impossible to state what would have happened to both the capital stocks and well-being in
624 the absence of the offshore wind industry. These issues could be overcome with more fine-
625 scaled analysis and improvements in the evidence base that are tailored towards well-being
626 assessments.

627

628 **6. Conclusions**

629 Drawing on peer-reviewed and grey literature, the framework developed in this study has
630 been used to evaluate the high level impacts of the offshore wind industry. It has proved a
631 useful tool for organising the evidence of the impacts on financial, manufactured, human,
632 social and natural capital. As changes in capital assets can be associated with change in a
633 number of human well-being domains, the framework allows for a more holistic evaluation
634 than is typical in such assessments, which usually focus on single or more limited number of
635 capitals and associated well-being outcomes. In general the impacts of the offshore wind
636 industry appear to be positive in the context of financial, manufactured and human capital,
637 if the current inputs can be assumed to result in well-being outcomes. They are more mixed
638 and less clear for social and natural capital, however. While further testing and refinement
639 of the framework is needed, especially at spatial scales where the evidence may be more
640 fine-grained, the framework could be easily transferred for well-being assessment of other
641 industries and interventions.

642

643 **Acknowledgements**

644 This research was funded by The Crown Estate, and we are very grateful to Prof. Mike
645 Cowling and colleagues for their comments on earlier drafts. We also thank the editor and
646 reviewer for helpful comments that have improved the paper.

1010

1011 Figure 1: Framework used to assess the well-being impacts of the offshore wind industry, combining a capitals approach, ecosystem services
 1012 and the well-being domains identified by the UK's Office for National Statistics (Randall et al., 2014). Arrows are indicative only.

1030

1031 **Table 1: Links between capitals, ONS well-being domains and evidence used to evaluate**
 1032 **the impact of the offshore wind industry.**

Link to capital	ONS well-being domain	Evidence available for the offshore wind industry
Financial Capital	The economy	Contribution to GDP
		Investments in supply chain and innovation support*
		Investment via price support and subsidies*
		Market stability*
Manufactured capital	The economy	Investment in manufacturing*
	What we do	Investment in manufacturing and infrastructure*
	Where we live	Infrastructure development
Human capital	What we do	Employment (direct, indirect and induced)
		Investment in knowledge generation*
		Employment impacts on non-offshore wind industries
	Education and skills	Skill level of employment
		Dedicated training courses
	Personal finance	Investment in research and development*
		Wage rates
Health	Safety of workers	
	Mental health within the community	
Social capital	Personal well-being	Level of support for offshore wind farms
	Where we live	Evidence of pro- and anti-offshore wind farm attitudes
		Community funds and projects*
Our relationships	Relationships within communities and with developers	
	Industrial relationships and networks	
Natural Capital	The natural environment	Provisioning ecosystem services: impacts on commercial fish stocks*
		Regulating and supporting ecosystem services: impacts on benthic communities*
		Cultural ecosystem services: impacts on charismatic species*
Not linked to capital, but provides enabling environment	Governance	Government - industry relationships
		Government/Local Authority - community relationships
		Industry-community relationships

1033 * Not an outcome indicator
